

Identifying High-Impact *Energy Reduction* Opportunities

An analysis of 5,580 Boston buildings to identify who faces the greatest compliance challenges — and where targeted intervention creates the highest impact.

PYTHON · PANDAS · 5,580 BUILDINGS · 54 VARIABLES

What BERDO requires

Boston's Building Emissions Reduction and Disclosure Ordinance mandates large buildings to report emissions and reduce operational carbon over time.

Data gaps are not random — they mark compliance risk

Property type is missing in a near-perfect pattern that maps directly onto compliance failure.

Different buildings need different solutions

The dataset reveals two non-overlapping intervention groups with fundamentally different needs.

EUI varies dramatically by building type

Laboratory and institutional buildings exhibit the highest energy use intensity, making them retrofit priorities.

1 in 4 buildings is high priority

Buildings with high EUI and high implementation complexity represent the toughest and most urgent retrofit targets.

Note: 96.51% of High Priority buildings are currently "In Compliance" — compliance status ≠ low energy use.

Three paths to meaningful emissions cuts

- Expand technical assistance**
Target condominiums, LLCs, and public-sector owners that face fragmented ownership and limited engineering capacity.
- Simplify the reporting process**
Missing data is a structural problem, not random noise. Proactive intervention beats reactive enforcement.
- Prioritize retrofit for high-EUI buildings**
1,003 high-priority buildings combine intense energy use with complex ownership — these need deep decarbonization pathways, not just compliance paperwork.
